Acrocanthosaurus atokensis Skull - Fossil Replica (BHI #126393)

This is the best replica skull available, from the rare and elusive Acrocanthosaurus, a meat-eating dinosaur from the Early Cretaceous. This replica is cast from the most complete skull ever found for this genus and species. The original skull is so complete that it has been described, to represent the entire genus and species. The skull is almost as long as Tyrannosaurus rex, yet much narrower. It appears to be very similar to, and almost as long as, Carcharodontosaurus from North Africa, and Gigantosaurus from Argentina.

Easily transported to off-site locations for outreach programs, promotional opportunities, etc.

Age Early Cretaceous

Locality Antlers Formation, McCurtain County, Oklahoma, USA

The original skeleton was prepared by Black Hills Institute and is now on display at the North Carolina Museum of Natural Sciences in Raleigh, NC, USA.

Notes Some geographic restrictions may apply. May take up to three months for delivery. Check with us to see if an earlier delivery is possible. Size ~ 56.5" l (144 cm) Extras Crate and packing fees apply. Please contact us for details.

Lease Info This item is leasable at 10% of listed price per month. See our rental page DinosaurRentals.com for more details.

Acrocanthosaurus skull cast Purchase price: \$9,500.00 (plus crating and shipping)

Acrocanthosaurus skeleton cast replica \$120,000.00 (plus crating and shipping).

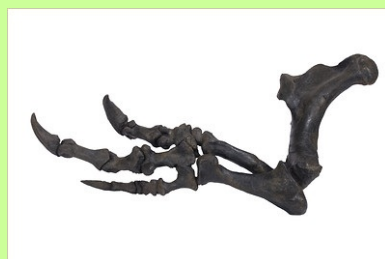

Please call (314) 503-9750(314) 503-9750 or [email us](mailto:info@taylor-made-fossils.com) for more pictures or information.

Acrocanthosaurus atokensis Right Arm - Fossil Replica (BHI #126392)

Acrocanthosaurus had the most powerful arms of any theropod that ever lived! This dinosaur is considered by most scientists to be the sauropod hunter in the trackway at Glen Rose, Texas.

This is a replica cast from the only complete arm from an Acrocanthosaurus. Displayed in a "grabbing pose", all of the muscle and tendon attachments are evident. Can be mounted on an optional steel base. Exhibit alone or with a group of other dinosaur arms.

Age Early Cretaceous
Locality Antlers Formation, McCurtain County, Oklahoma, USA

The original skull and skeleton were prepared by Black Hills Institute and is now on display at the North Carolina Museum of Natural Sciences in Raleigh, NC, USA. Notes: May take up to four weeks for delivery. Check with us to see if an earlier delivery is possible. Size ~ 39" l (99 cm)

Price: \$1,450.00 (no stand)

\$1,500 (with display stand)

Please call (314) 503-9750(314) 503-9750 or [email us](mailto:info@taylor-made-fossils.com) for more pictures or information.

Albertosaurus sarcophagus skeleton cast replica

Albertosaurus sarcophagus skeleton cast replica \$59,900 (plus shipping)

Albertosaurus sarcophagus skull and skeleton cast replicas.

This beautiful specimen was molded from fossils discovered in the Two Medicine Formation, Teton County, MT, US. The originals are now in the Museum of World Treasures, Wichita, KS, US.

The Skeleton cast measures: 20' long and 7.5' w (at the hips) or 6 m x 2.5 m at the hips.

The Skull cast measures 32" x 18" x 12"

Please call (314) 503-9750(314) 503-9750 or [email us](#) for more pictures or information.

Allosaurus skull #2

The Allosaurus is one of the most famous dinosaurs ever discovered, and this exceptional fossil is a perfect representation of this legendary predator.

This specimen is from a full grown adult, and it measures 35L"x14W"x18H". It is cast in resin which yields extremely realistic texture.

Customer reviews: *"The detail on the teeth is just fantastic!"*

"It is wonderful! The color, texture, detailing are even better than your catalogue photographs. Thank you for your good business and integrity. You've have made me a customer for life"

"Thank you for a fine specimen!"

Our allosaurus skull was featured in a recent episode of HBO's "Entourage"

Allosaurus skull #2 resin cast: \$950 plus shipping.

UPS Shipping will be \$75 within the U.S. We will gladly ship it anywhere in the world (shipping cost worldwide is based on weight and size. Shipping weight approx. 45 lbs). This skull takes approx. 7-10 days to prepare. A perfect last minute gift!

Please call (314) 503-9750(314) 503-9750 or [email us](#) for more pictures or information.

Alxasaurus elesitaiensis skeleton cast replica

Alxasaurus (pronounced AWL-shah-SAWR-us) which means "Alxa Desert lizard" is a genus of therizinosauroid theropod dinosaur. From the Early Cretaceous of Inner Mongolia. It is one of the earliest known members of the superfamily Therizinosauroidea, but it still possessed the body shape - including the long neck, short tail, and long hand claws - of later therizinosauroids. Like other members of this group, it was a bipedal herbivore with a large gut to process plant material. Several specimens are known and the largest was a little over 12 feet (3.8 m) long.

Alxasaurus elesitaiensis skeleton cast replica

Early Cretaceous.

Molded from an original fossil discovered in Alashan, Neimenggu

neoceratopsian dinosaur from the Early Cretaceous (Aptian stage) of north central China.

Unlike many other ceratopsians it had no horns, possessing only a small bony frill projecting from the back of its head.

Superorder: Dinosauria, Order: Ornithischia, Suborder: Cerapoda, Infraorder: Ceratopsia, Family: Archaeoceratopsidae, Genus: Archaeoceratops

Arstanosaurus Skull cast replica

Arstanosaurus Skull cast replica. *Arstanosaurus* pronounced: *Ahr-stan-oh-SAWR-us* was discovered in Baishin Tsav, Gobi Desert, Southeastern Mongolia

Arstanosaurus is from the Late Cretaceous (Santonian), Bayn Shireh Formation.

This skull measures 5.51 inches (140 mm).

The name "*Arstanosaurus*" means: "Reptile from Arstan well"

[Photo of top of skull](#)

Classification: Ornithopoda: Hadrosauridae; Hadrosaurinae

Studies of the microstructure of the bones suggest that the young grew rapidly attaining a height of 40-50 centimetres in the first year after hatching.

This skull is that of a young hadrosaurid or duck-billed dinosaur, possibly aged 3-4 years. Adults were probably 6-7 metres high and up to 15 metres long.

Resin cast: \$160 USD

Avimimus skeleton cast replica

Avimimus (A-vee-MIME-us)

Complete skeleton discovered in Udan Sayr, Gobi Desert, Mongolia

Late Cretaceous (Campanian), Djadokhta Formation

This skeleton measures 4 ft 9 inches long (1.5 meters)

Theropoda: relationships uncertain

Avimimus, means 'Bird mimic'. It was interpreted by its discoverer, Dr Sergi Kurzanov, as a dinosaur that had features in parallel with birds, perhaps even feathers. The animal possibly had short, wide wings of limited use for flight and may even have been warm blooded. The foot of Avimimus is compared with that of the large carnivorous dinosaur, Tarbosaurus and the similarities are clear. The middle metatarsal bone is very reduced in both.

Bactrosaurus johnsoni Skeleton cast #2 Juvenile

Bactrosaurus johnsoni Skeleton cast #2.

This is a juvenile specimen measuring: 7ft l x 3ft h (2.13m l x .9m h). Discovered in Mongolia, China. Late Cretaceous, Mongolia, China.

Bactrosaurus johnsoni was an unusually small, herbivorous dinosaur. They may have lived in small groups for protection, and near dense vegetation to avoid being detected by hunting carnivores. This important hadrosaur maintains many primitive skeletal features. It is classified near the lambeosaurinae group despite its lack of a cranial crest.

This skeleton is accurately reconstructed, cast in solid urethane, and finished to look like the original fossil. This example is mounted in a walking position however, it can be ordered in various poses to reproduce a small herd.

Skeleton \$11,975

Bagaceratops rozhdestvenskyi skull cast replica

Bagaceratops rozhdestvenskyi (*Bag-a-CER-a-tops*) whose name means 'Small horned face' was discovered in Khermin Tsav, Gobi Desert, Southern Mongolia

Late Cretaceous (Campanian), Barun Goyot Formation

Adults of this species grew up to 1 metre long (3.28 feet)

Classification: Ceratopsia: Neoceratopsia; Protoceratopsidae

This specimen of *Bagaceratops rozhdestvenskyi* is one of the smallest skulls known of a dinosaur. The large orbits suggest it was a juvenile. Related to *Protoceratops andrewsi*, this protoceratopsian was somewhat smaller, the skulls of the adults never exceeding 25 cm (9.8 in) in size.

A bony knob on the face, a precursor for the well-developed horns of the larger ceratopsians, was more prominent than that in *Protoceratops andrewsi*, but the frill was less elaborately developed. So, in one feature *Bagaceratops rozhdestvenskyi* was more advanced than *Protoceratops andrewsi* but in others, more primitive. It possessed a mixture of advanced and primitive characteristics.

As with other neoceratopsians, *Bagaceratops* had a sharp beak at the front of the jaws and a row of leaf shaped teeth behind. Below each tooth that erupted along the edge of the jaw was a waiting line of unworn teeth under the 'gums' so that these little dinosaurs were able to feed on very tough vegetation without wearing out their tooth supply.

Brontotherium Titanothere skull replica

Brontotheriidae, also called Titanotheriidae, is a family of extinct mammals belonging to the order Perissodactyla, the order that includes horses, rhinoceroses, and tapirs. Superficially they looked rather like rhinos, although they were not true rhinos and are probably most closely related to horses. They lived until the very close of the Eocene.

Dimensions of the fossil skull replica: 26" long x 13" wide x 24" tall.

The skull and lowers are from Custer County, SD. The skull (upper) was collected on a cattle ranch in 1992 and the lowers found in the same area but, later in 1999.

Brontotherium skull cast (shown here unpainted/untrimmed)

TaylorMadeFossils.com

Titanothere skull replica – *Brontotherium* Brontops

Brontotheres have teeth adapted to shearing (cutting) relatively nonabrasive vegetation. Their molars have a characteristic W-shaped ectoloph (outer shearing blade).

The history of this group is well known, due to an excellent fossil record in North America. The earliest brontotheres, such as *Eotitanops*, were rather small, no more than a meter in height, and were hornless.

Brontotheres had massive body sizes, although some small species, such as Nanotitanops did persist through the Eocene. Some genera, such as Dolichorhinus, evolved highly elongated skulls. Later brontotheres were massive in size, up to 2.5 m (8.2 feet) in height with bizarre hornlike skull appendages. For instance the North American brontothere Megacerops had large sexually dimorphic paired horns above their noses. The sexually dimorphic horns suggest that brontotheres were highly gregarious (social) and males may have performed some sort of head clashing behavior in competition for mates. However, unlike rhinos, the horns of brontotheres are composed of bone, the frontal bone and nasal bone, and were placed side-to-side rather than front-to-back.

Brontotheres probably became extinct due to an inability to adapt to drier conditions and tougher vegetation (such as grasses) that spread during the Oligocene.

Calf: *Bos Taurus* with Craniofacial duplication

© Bone Clones® 2006

©Copyright Bone Clones® 2006

Two heads, fused, but one endocranium and one foramen magnum that connected to a single neck and body. A very rare and beautiful specimen considering that the skulls are literally mirror images of one another. It appears to have been artistically created but really was molded and cast from a real skull. Custom Stand included.

This calf exhibits the rarest form of conjoined twinning known as Diprosopic Parapagus. This bizarre congenital defect results from the complete fusion of the bodies, limbs, necks and rear portions of the skulls of identical twins, with only their "faces" remaining to reveal their individual origins.

We had to show the underside of this unique specimen. Both mandibles were cast separately and attached to the skull in the correct anatomical position to match the original skull.

Cast measures: 8" Wide, 9" Long, 5" Deep

Two-faced Calf (Craniofacial duplication)

 Add to Cart

Deinosuchus (pronounced DYE-no-SOO-kəs) is an extinct relative of the alligator. Late Cretaceous. The name translates as "terrible crocodile" and is derived from the Greek *deinos* ("terrible") and *soukhos* ("crocodile"). The first remains were discovered in North Carolina in the 1850s.

Deinosuchus was far larger than any modern crocodile or alligator—measuring up to 12 m (40 ft) and weighing up to 8.5 metric tons (9.4 short tons)—its overall appearance was fairly similar to its smaller relatives. It had large, robust teeth that were built for crushing, and its back was covered with thick semispherical osteoderms. One study indicates that *Deinosuchus* may have lived for up to 50 years, growing at a similar rate to that of modern crocodylians, but maintaining this growth over a much longer period of time.

Deinosuchus fossils have been found in ten U.S. states, as well as northern Mexico. It lived on both sides of the Western Interior Seaway, and was an opportunistic apex predator in the coastal regions of eastern North America.

Kingdom: Animalia, Phylum: Chordata,
 Class: Sauropsida, Order: Crocodylia,
 Suborder: Eusuchia, Superfamily:
 Alligatoroidea, Genus: *Deinosuchus rugosus*

Deinocheirus arms \$9,500 (plus shipping)

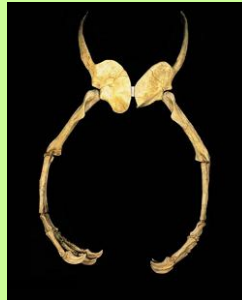

Qty
 Add to Cart

For many years *Therizinosaurus cheloniformis* and *Deinocheirus mirificus* presented palaeontologists with a puzzle. Evidently somehow related to the theropods or carnivorous dinosaurs, the function of their large claws and their attendant forelimbs was a mystery. Certainly, they had to belong to animals quite unlike *Tarbosaurus bataar* with its highly reduced forelimbs and yet they were animals clearly in the same size category.

Material that has recently come to light in China suggests that these animals were as atypical of large carnivorous dinosaurs as pandas are atypical of bears.

Like pandas, they were probably gentle herbivores. They used their large forelimbs and claws to pull down branches on which to browse. The claws with the horny sheath that would have fitted over the outside of the bone may have been up to one metre long.

Some palaeontologists have even suggested that *therizinosaurus* may have used the huge claws for ripping into ant nests.

Locality: Gobi Desert, Southern Mongolia
 Age: Late Cretaceous (Late Campanian-Early Maastrichtian), Nemegt Formation.

Size: *Therizinosaurus* arms were about 2.5 metres long, scythe-like claw 70cm long around its outer curve / *Deinocheirus* arms about 2.6 metres long

Meaning of Name:
Therizinosaurus: Scythe reptile. *Deinocheirus*: "Terrible hand"
 Pronunciation: *Ther-ih-sen-oh-SAWR-us; Dine-oh-KIR-us*
 Classification:
 THEROPODA: relationships uncertain

The picture of *Therizinosaurus cheloniformis* and *Deinocheirus mirificus* as browsers in a forest agrees well with the view that conditions in Central Asia had become much more moist than what they had been like years before.

Dimetrodon, pronounced (die-MET-roh-don) which means ("two measures of teeth" so named because it had a large skull with two different types of teeth; shearing teeth and sharp canine teeth, unlike reptiles. Dentition showing this differentiation of teeth is called heterodonty).

Dimetrodon has a large sail which was probably used to regulate body temperature; the surface area would allow it to warm up or cool off more efficiently. Dimetrodon was not a dinosaur but a pelycosaur, an early synapsid (mammal-like reptile).

Dimetrodon BYU skeleton

Dimetrodon Limbatus skeleton. This wonderful Dimetrodon skeleton is the BYU specimen. A carnivorous mammal-like reptile from the Permian. Discovered in Texas, USA.

Dracorex hogwartsia "Dragon King" Cast Reconstruction

Recently featured on the cover of National Geographic December 2007 (BIG BAD DINOSAURS) Dracorex hogwartsia is a brand new dinosaur species.

Type Species - Dracorex hogwartsia, From the late Cretaceous of North America. Etymology - from the Latin words: draco (meaning dragon) + rex (meaning king). translation: "dragon king"

This skull is the same species as holotype - TCM1 2004.17.1

Named after the fictional "Hogwarts Academy," from the Harry Potter series.

This is the first replica available for Dracorex hogwartsia! This profile contains the dentary and pre-dentary. The front teeth are serrated, looking as if this may be the first evidence of an omnivore! This replica is cast in solid resin and is made to hang on a wall or rest on a table.

Family: Pachycephalosauridae
Genus: Dracorex

Dracorex hogwartsia Skull (Left Profile In-Situ)
Restored Skull from the Left View, Entire tooth row!

Skull measures 13 inches high and 20 inches long.

Dromaeosaurus albertensis skeleton cast replica

Dromaeosaurus albertensis Skeleton cast replica.

Measures: 8' l x 3' w (2.28m l x .91m w) \$12,500

(Late Cretaceous, Alberta, Canada)

Dromaeosaurus albertensis is one of the rarest theropods from the American west. They were closely related to Velociraptor but significantly larger. Known only from a collection of partial skeletons, this specimen represents the latest interpretation of its anatomy, composited from several individuals.

Fast, agile and vicious, Dromaeosaurs may well have hunted in packs, preying upon the smaller herbivores and probably the sick and young of larger dinosaurs. Attacking with their lethal "killing claw", they were able to inflict mortal wounds on their prey, and then wait for them to expire. Dromaeosaurs make an impressive exhibit as a pack in hunting mode.

Please call (314) 503-9750(314) 503-9750 or [email us](#) for more pictures or information. .

Duck Bill dinosaur skull cast: Saurolophus angustirostris

Duckbill
Dinosaur skull
Saurolophus angustirostris
Discovered in
Mongolia,
Nemegt
formation
Age: Late
Cretaceous

Saurolophus
(meaning
"reptile crest") is
a genus of large
hadrosaurine
duckbill dinosaur
that lived in
North America
(Canada) and
Asia (Mongolia);
it is one of the
few genera of
dinosaurs known
from multiple
continents.

Resin cast measures: 14 x 29 x 7 Inches

\$675 ~~Sale \$660~~ (cast)

Qty

[Add to Cart](#)

Saurolophus is distinguished by a spike-like crest which projects up and back from the skull. Saurolophus was a herbivorous dinosaur which could move about either bipedally or quadrupedally.

The distinctive spike-like crest of Saurolophus has been interpreted in multiple ways, and could have had multiple functions. Brown suggested it could provide an area for muscle attachment and a connection point for a nonbody back frill like that seen in the basilisk lizard. Peter Dodson interpreted it as having use in sexual identification. Maryanska and Osmolska, noting the hollow base, suggested that the crest increased the surface area of the respiratory cavity, and helped in thermoregulation. James Hopson supported a function as a visual signal, and further mentioned the possibility that there were inflatable skin flaps over the nostrils that could have acted as resonators and additional visual signals.

Fossil discovered: Sokolki, Malaya Severnaya (Small North) Dvinia River near Archangel'sk, Northern Russia.

Late Permian, Zone IV

Classification: Therapsida: Cynodontia; Family Dviniidae This small, omnivorous therapsid is clearly advanced in having a temporal opening so large that on only a thin bar of bone remains to separate it from the eye socket.

Therapsids' temporal fenestrae were larger than those of the pelycosaurs. The jaws of therapsids were more complex and powerful and the teeth were differentiated into frontal incisors for nipping, large lateral canines for puncturing and tearing, and molars for shearing and chopping food. Therapsids' legs were positioned more vertically beneath their

bodies than were the sprawling legs of reptiles and pelycosaurs.

Edmontosaurus annectens skeletons cast replicas

Edmontosaurus annectens skeletons cast replicas.

Two truly beautiful Edmontosaurus skeletons, adult and juvenile.

The adult measures 24 feet long (7.31m)

The juvenile skeleton measures 15 feet long (4.57m)

Edmontosaurus (adult) \$70,850 skeleton cast replica

Edmontosaurus (juvenile) \$42,900 skeleton

Apparently our adult Edmontosaurus survived an attack from a theropod, which left deep gouges in the right dentary and shallower gouges in the left dentary. The Edmontosaur may have pulled away from its attacker, causing the deep wounds. Close examination suggests that the wounds may have begun to heal, leading to the possibility that it survived the attack for awhile, only to succumb to infection and die a short while later.

Custom painted to your specifications

Edmontosaurus resembled Maiasaura (see Maiasaura below) in its shape and posture, though the two genera were quite different in size. We have access to Edmontosaurus skulls and skeletons (please inquire).

Einosaurus procurvicornus Dinosaur skull

Photo above is for comparison only. This is an Einosaur skull that was recently up for auction. You can compare it to the pictures on the left (and below) and you will see how nicely this skull will look with a little restoration.

Legally collected, this skull comes with pictures, and details of the discovery. It was found in a ravine with a herd that died from a sudden flood. It is one of most unusual dinosaurs that ever lived and it may have gone extinct due to the horn pointing down (and not being able to use it for defense).

Few remains have been found of this animal and most museums do not have any remains of this animal. There are very few people who have this is private collections - so your purchase will make you among the most rare of museums or collectors.

This sub-adult skull measures 44". This is an opportunity to get a great skull for an economical price. I fell in love with this dinosaur the second I saw it. It is just beautiful. Displays well on top of a table or any piece of furniture and can safely be carried by two people. I can't say enough about this dinosaur. It is beyond words. Call for more details on this one.

Price: \$21,900

Einosaurus (hooked nose horn). This is a very rare *Einosaurus procurvicornus* (Einiosaurus) skull with all 3 horns.

This is a fairly new discovery (1985) it was named in 1995 and is called "buffalo lizard". It is a medium-sized centrosaurine (short-frilled) ceratopsian from the Upper Cretaceous. Compared to Triceratops, the Einosaur had a short-frill.

Einosaurus was a herbivore. Though a sub adult, this Einosaur would have grown to about 20 ft long.

Geological Formation: Two Medicine Formation

Location: Discovered 2 miles from the Canadian border north of Dupuyer, Montana NW Montana. All previous Einosaurus fossils have been found in Canada.

This is a very rare dinosaur skull. Very few have been discovered. This skull is the complete upper skull with braincase. It is missing some frill behind dinosaur's right eye and also the lower jaw. The skull itself has no restoration (only crack filling). The nose horn measures 23 inches. The nose curves downward like a can-opener.

Einosaurus had 2 horns off the frill. Though not attached, this skull comes with two horns. One of these was discovered with the skull, the 2nd comes from a slightly larger member of the same dinosaur. It is a good match for size. These horns are not connected to the skull but can be with a little restoration.

We have seen reconstructed skulls of this dinosaur go for \$50,000 to \$60,000 while still in the ground!

Please call (314) 503-9750(314) 503-9750 or [email us](#) for more pictures or information.

Elephant skull (*Platybelodon grangeri*)

Platybelodon Elephant Skull with base

This skull belongs to a now extinct relative of elephants called *Platybelodon grangeri*. *Platybelodon* (meaning "flat-tusk") lived during the Miocene Epoch. It may have gone extinct from overspecialization and inability to adapt to changing environmental conditions.

The shape of the two lower teeth have led *Platybelodon* to be known as a "shovel tusker". It may have used it's teeth to strip bark from trees. This specimen was discovered in Gansu Province, China and measures 53" long. Late Miocene.

Iguanodon orientalis skull

Iguanodon orientalis skull

Iguanodon means "Iguana tooth". It is classified as:
**ORNITHOPODA;
Iguanodontia;
Iguanodontidae**

**Early Cretaceous
(Aptian), Barum Bayan**

Iguanodon orientalis from Mongolia (above) is

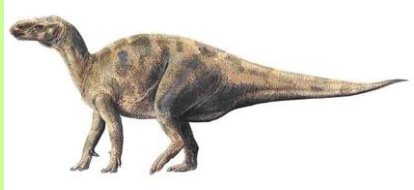

Formation

Discovered in the Gobi Desert, Southwestern Mongolian Peoples' Republic.

Its hands had four fingers and a spike-like thumb, which it may have used to defend itself. Its teeth are reminiscent of those in hypsilophodonts, flattened side to side, and leaf-shaped. They probably sliced up plant material like a pair of scissors.

Because of the large number of skeletons of these dinosaurs frequently found together and evidence from fossil track ways, palaeontologists think they may have formed herds. Their remains are most often found in sediments deposited in swampy, lake and river edge environments suggesting that is the place they spent most of their time munching on horsetails (like the living Equisetum), ferns, cycads and various kinds of conifers.

very similar to iguanodonts from Europe (below) except for its huge, bulbous 'nose.' This hollow structure may have been used as a resonating chamber for making 'dinosaur music or mating calls.

This skull measures 90cm in length

Cast in resin.

Lotosaurus adentus skeleton cast replica.

Middle Triassic

Lotosaurus is an extinct genus of rauisuchian archosaur that lived in China. It was a heavily built quadruped. It was a herbivore, biting off leaves with its toothless jaws. *Lotosaurus*, like other members of the family Ctenosauriscidae, had a sail on its back. It looked similar to that of Permian pelycosaurs like *Dimetrodon* and *Edaphosaurus*, although not as high. It may have been used for display and/or body temperature regulation.

Purchase price Lystrosaurus youngi skull \$3,200

Lystrosaurus skeleton

Lystrosaurus (Lis-trow-SAWR-us).

This skeleton was discovered in Astashikha, Nizhegorodskaya Region, Russia in Early Triassic sediments.

The skeleton measures about 1 metre (aprox 3 1/2 feet) long. The name *Lystrosaurus* means 'Shovel reptile'

Classification:
Therapsida:
Anomodontia;
Lystrosauridae

Lystrosaurus has long been known from many parts of the world, although it has yet to be found in Australia.

As in another mammal-like reptiles *Dicynodon*, ("Two Dog-teeth") the teeth of *Lystrosaurus* were reduced to a pair of tusks. Both of these reptiles appear to have been herbivores.

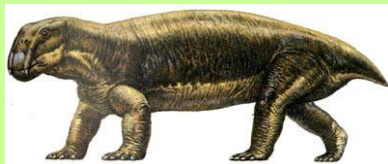

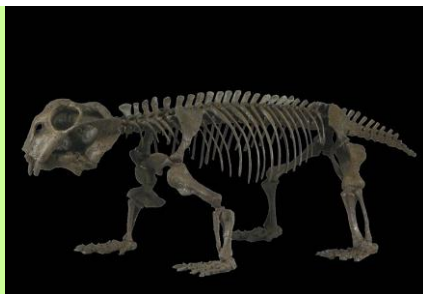

The structure of the skull, with the nostrils and eye sockets placed near the top of the head, the snout turned down at the tip and the teeth and jaws placed low, all suggest that *Lystrosaurus* was an amphibious feeder, in much the same fashion as the hippopotamus.

Resin cast: Price \$5,400

***Macrauchenia* Skull**

***Macrauchenia* Skull**

The first *Macrauchenia* (which means "Big neck") fossils were discovered by Charles Darwin during his voyage of the *Beagle*.

The last of its line, *Macrauchenia* was the final member of South America's unique native hoofed animals, which have not been studied much since their

discovery. The strangest feature is *Macrauchenia's* skull, with nostrils right up on top of the head. This led to all sorts of suggestions, including the idea that they were aquatic, using these nostrils as a blowhole. The most likely explanation, though, is that they had a tapir-like proboscis, giving them a 'hose nose'.

Scientific name:
Macrauchenia, sp

The lower jaw measures: 50x 50cm. We have tusks available (either real or replicas)

Mammoth fossil skeleton #1 (Real fossil not a cast)

Mammoth skeleton #1

This is a real Mammoth skeleton (not a cast).

Price starting at \$99,000 depending on which skeleton you choose. I have several to choose from.

We also have a cast of *Mammuthus primigenius* skeleton available (\$85,000 skeleton or \$8,500 skull). This is the largest most complete wooly mammoth ever found in North America. I will gladly [email](#) you pictures of all.

Marasuchus / Marasaurus Dinosaur cast Skeleton plaque

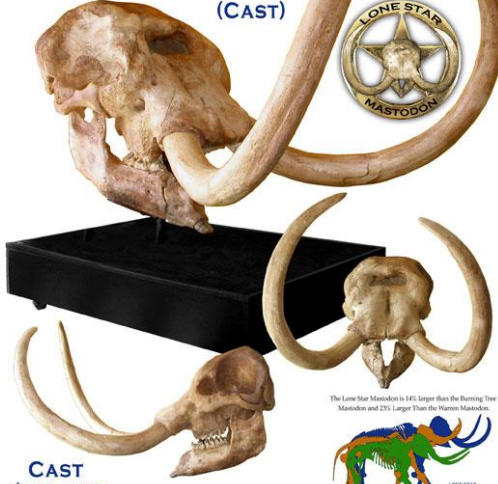

Marasuchus is a genus of dinosaur-like ornithomimid from the middle Triassic Period of Argentina. The species *Marasuchus illoensis* was originally described as a second species of *Lagosuchus*, *L. illoensis*. However, in a restudy of *Lagosuchus* by Sereno and Arcucci (1994), the authors concluded that the original (type) specimen was too poorly preserved to allow any further specimens to be assigned to the genus. They also noted that the *L. illoensis* specimen had limb proportions different from the type species. On this basis, they assigned *L. illoensis* to a new genus, *Marasuchus*.

Resin cast measures approx 3 1/2 by 4 feet.

Pawpawsaurus campbelli (Nodosaurid ankylosaur)

This new Dinosaur species was found in 1992 by Cameron Campbell. Pawpawsaurus, meaning "Pawpaw Lizard", is a nodosaurid ankylosaur from the Cretaceous of Tarrant County, Texas, discovered in May 1992. The only species yet assigned to this taxon, Pawpawsaurus campbelli, is based on a complete skull (lacking mandibles) from the marine Paw Paw Formation (Wachita Group).

This is the only nodosaurid known to have possessed the bony eyelids commonly found in ankylosaurids. Based on the dimensions of the skull, Pawpawsaurus is believed to have been approximately 15 feet long.

Pawpawsaurus campbelli, nodosaurid ankylosaur skull cast replica

Measures: 9.5"L, x 7.25"W x 5"H

Scientific Name: *Pinacosaurus grangeri*

Discovered in Mongolia in the Djadochta Formation.

Late Cretaceous

Skull measures 12"

Resin cast: \$450

Qty

Add to Cart

Pinacosaurus was a lightly-built, medium-sized ankylosaur with a long skull, that reached a length of 5 meters (16 ft). Like all ankylosaurids, it had a bony club at the end of its tail which it used as a defensive weapon against predators such as *Tarbosaurus*. The most unusual element in the original specimen is the presence of two additional egg-shaped holes, one on top of the other, where the nostrils are normally found. The openings are characteristic of the genus, and the number varies: Godefroit *et al.* described four in 1999, and in 2003 a juvenile specimen with of five pairs of openings was described.

Pinacosaurus grangeri juvenile skull cast replica

***Pinacosaurus* juvenile skull cast with base**

Scientific Name: *Pinacosaurus grangeri*

Pinacosaurus ("blank lizard") is a genus of medium-sized ankylosaur dinosaurs whose fossils are found in the late Santonian to the late Campanian of the late Cretaceous, in Mongolia and China. *Pinacosaurus* had between two and five additional holes near each nostril, which have not been explained.

This skull was discovered in Mongolia in the Djadochta Formation.

Measures 5.5"

Plesiosaurus dolichodeirus

Plesiosaurus dolichodeirus skeleton cast replica panel.

This skeleton cast is made of resin/fiberglass and measures 72x30 inches.

\$900 (we also have one available at a reduced price please inquire)

Plesiosaurus (pronounced: plee-zee-oh-SAWR-us). It's name comes from the Greek: *plesios*, which means "near to" + *sauros*, meaning: "lizard"). *Plesiosaurus* was a large (about 3 to 5 meters long), marine Sauropterygian reptile that lived during the early part of the Jurassic Period, and is known by nearly complete skeletons from the Lias of England and Germany. It was distinguished by its small head, long and slender neck, broad turtle like body, a short tail, and two pairs of large, elongated paddles. It lends its name to the order Plesiosauria, of which it is an early but fairly typical member.

Plesiosaurus was one of the first of the "antediluvian reptiles" to be discovered (by Mary Anning), and excited great interest in Victorian England. It was so-named ("near lizard") by William Conybeare, to indicate that it was more like a normal reptile than *Ichthyosaurus*, which had been found in the same rock strata just a few years previously.

Each cast is hand made and hand painted. As a result, the color of casts may vary slightly.

Prenocephale prenes

Prenocephale prenes

Classification: Pachycephalosauria;
Pachycephalosauridae

Pachycephalosauridae and Homocephalidae *Prenocephale prenes* and *Homalocephale calathocercos* are both pachycephalosaurids, literally 'thickheads'.

The top of their skulls were 8 to 10 centimetres thick, solid bone apparently protecting a walnut-sized brain. This thickening of the skull has been interpreted as allowing these animals to act like the living mountain sheep in which the males compete for females by holding head-butting contests.

In addition to the domed heads other indications that these dinosaurs head butted can be seen in the stiff spinal column, thus giving it strength for the forces applied when contact occurred, and the angle of articulation of the skull and the neck vertebrae-which puts the head in just the right position to make butting safe and not a back-breaking exercise.

These dinosaurs have very small teeth with serrated crowns, ideal for shredding plant material.

Pachycephalosaurids may have had a lifestyle very like that of modern sheep and goats and even may have moved about in small herds.

Prenocephale prenes skull cast replica (ZPAL MgD-I/104)

Pronounced: *Pre-know-CEPH-ah-lee, Home-al-oh -CEPH-a h-lee*

This specimen is from the Late Cretaceous (Late Campanian-Early Maastrichtian). It was discovered in the Nemegt Formation of the Gobi Desert, Nemegt, Mongolia

I also have several Real psittacosaur skeletons available

Psittacosaurus meileyingensis skeleton unassembled

I also offer the Psittacosaurus Skeleton unassembled. As unassembled skeletons go, this one is relatively easy. The cast comes unpainted as seen in the picture, and can be colored with just about any kind of paint (oil paints, or stain is recommended). The pieces can be glued or wired together.

A steel rod (which you can purchase at a hardware store) can be used for the spine as seen in these photos from a customers assembly.

This skeleton comes with several photos showing a range of steps in the assembly.

Bone Clones cast

TaylorMadeFossils.com

With an estimated body length of 40 feet, and a skull over 5 1/2 feet long, Supercroc is one of the largest crocodiles that ever walked the Earth. The Sarcosuchus's jaws are lined with over 100 teeth. Unlike modern crocodylians whose teeth interlock, Supercroc's lower teeth fit inside its uppers, leading scientists to the conclusion that Sarcosuchus imperator did not limit its diet to fish. It is believed that Sarcosuchus was an ambush predator capable of killing large dinosaurs that wandered too close to the water's edge. The Sarcosuchus's unusual bulbous snout is thought to have given it a greater ability to smell prey and make louder sounds. This gigantic crocodylian was first discovered in the Sahara desert by Albert-Felix de Lapparent (1964) and named by France de Broin / Phillipe Taquet (1966).

Scutosaurus skeleton cast replica

Scutosaurus
Pronounced: *Skew-toe-SAWR-us*

The name means: Shield Reptile

Classification:
Parareptilia:
Pareiasauroidea;
Pareiasauridae

Discovered in Sokolki, Malaya Severnaya (Small North), Dvina River near Archangel'sk, northern Russia

Age: Late Permian, Zone IV

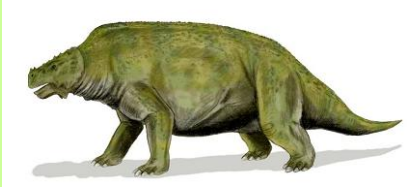

This skeleton measures about 1 metre (100 cm) long

Skeleton of a herbivorous scutosaur, a primitive reptile. Several skeletons of this large animal were found together in a flood channel sand deposit by Prof. V. P. Amalitzky.

Scutosaurus ("shield Reptile") was a genus of armor-covered pareiasaur, perhaps as much as 3.5 m long, which lived in Russia, in the later Permian period. Its genus name refers to large plates of armor scattered across its body. It was a large anapsid reptile that, unlike most reptiles, held its legs underneath its body to support its great weight.

Resin cast replica \$4,425.00* USD (\$4,610.00 AUD) (or less please inquire). Skull also available separately.

Sloth: *Paramylodon harlani* Harlan's Ground Sloth Skeleton cast replica

Harlan's Ground Sloth Skeleton

Paramylodon harlai Harlan's Ground Sloth Skeleton cast replica.

Paramylodon is an extinct genus of ground sloth known from North America deposits in Mexico and the United States. Currently there is just one recognized species, *P. harlani*, that is commonly referred to as Harlan's ground sloth in honor of American paleontologist Dr. Richard Harlan who first discovered and described a lower jaw in 1835. *Paramylodon* exhibits an interesting character of having had dermal ossicles, small bones embedded in the skin. This would have provided an interesting degree of protection to the animal, and this character is also shared by the South American *Myiodon*.

Sloth skeleton cast replica skeleton. Cast in Polyurathane from an original fossil, from Late Pleistocene Rancho La Brea LACMNH license.

Kingdom: Animalia, Phylum: Chordata, Class: Mammalia, Superorder: Xenarthra, Order: Pilosa, Family: Mylodontidae, Subfamily: Mylodontinae, Genus: *Paramylodon*, (Brown, 1903) Species: *P. harlani*

Struthiomimus full skeleton mount cast replica

Struthiomimus
Translation:
Ostrich Mimic.
Struthiomimus (strooth-ee-oh-MIME-us) was a long-legged, ostrich-like dinosaur of the family Ornithomimidae, which lived in the area that is now Alberta, Canada. Its generic name is derived from a Greek word meaning "ostrich" and also a word meaning "mimic" or "imitator". The specific name *altus* is from Latin, meaning "lofty" or "noble".

This skeleton is 15 ft long and 6 ft tall at the hips **Struthiomimus** skeleton cast replica. New price: \$45,000

Struthiomimus Skull cast replica

Struthiomimus Skull (Margie)

This Delicate and fascinating specimen is made entirely of resin and was found near Glendive, MT. It weighs a mere 1lb. and measures 12"x4"x6".

Struthiomimus (meaning "ostrich mimic", from the Greek *strouthion* meaning "ostrich" and *mimos* meaning "mimic" or "imitator") is a genus of ornithomimid dinosaur from the late Cretaceous of Alberta, Canada. It was a long-legged, ostrich-like dinosaur.

The bipedal **Struthiomimus** stood about 14 ft long (4.3 meters) and 4.6 ft (1.4 meters) tall at the hips and weighed around 330 lb (150 kilograms). **Struthiomimus** is one of the more common small dinosaurs in the Dinosaur Provincial Park; its abundance suggests that it was a herbivore or omnivore rather than a carnivore.

Struthiomimus Right hand cast

Struthiomimus : Right hand of **Struthiomimus**

The original fossil of this **Struthiomimus** was found in the Hell Creek Formation near Glendive, Montana. The original skeleton found was about 60% complete.

Struthiomimus Right hand cast. Please contact us for price:(314) 503-9750(314) 503-9750 call or [email](#) us.

We also take checks, money orders and credit cards.

Titanichthys Skull cast replica

Titanichthys agassizi was a giant, aberrant marine placoderm from the Late Devonian. It approached *Dunkleosteus* in size and build. Unlike its relative, however, *T. agassizi* had small, ineffective-looking mouth-plates that lacked a sharp cutting edge. It is presumed that the beast used its capacious mouth to swallow or inhale schools of small, anchovy-like fish, or

Please
contact
us for
pictures.

possibly krill-like zooplankton, and that the mouth-plates retained the prey while allowing the water to escape as it closed its mouth.

When the first specimens were found in Morocco by geologist Henri Termier, Titanichthys was originally placed within the genus Gorgonichthys - that is, after Termier was able to convince his colleagues that the bone scraps were of a placoderm, and not a A junior synonym is *Brontichthys*, which should not be confused with another arthrodire, *Bruntonichthys* (Dinichthyidae).

Late Devonian

Triceratops (Baby) Replicas

Baby Triceratops Replicas Available

In 2006 near Jordan, Montana, a triceratops quarry was discovered. The quarry contained a sub-adult triceratops partial skull and skeleton, and elements from a baby triceratops. The first two elements from the baby that were found were the left humerus and the right dentary. The humerus (6.25" long) was complete and dentary was 50% complete. As preparation continued on the sub-adult material, the left dentary was discovered! This one was complete, allowing for the length of the dentary to be known (5.25 inches)! With the left one found complete, the right one could be reconstructed.

Now, these very rare and unique replicas are available. Each dentary has a tooth in it. This is truly a unique set of replicas. With these elements, it can be estimated how big the triceratops was. It is guessed to be under 3 feet long, with a skull less than 12 inches!

They were found near Jordan, Montana and in the world famous Hell Creek Formation. This formation is upper cretaceous.

The first Tyrannosaurus rex was collected within 100 miles of the site by Barnum brown over 100 years ago.

Triceratops Brow Horn #2

Like antlers and horns on modern day mammals, Triceratops horns were probably used more for show (and thus mate selection) than for defense.

But if you would rather forget we said that and instead reminisce on the more romantic "T. rex versus Triceratops" concept, we'll understand.

And its important to remember that much speculation goes into recreating the life of dinosaurs so Triceratops may have indeed defended itself with those massive, reinforced horns.

Triceratops of course had three horns, two on it's brow and another smaller horn behind it's snout. When you hold these giant bones in your hands, consider that only the inner cores are preserved as fossils. In life, these structures would have been sheathed in a hard, shiny horn. Truly this was an awesome tool for one incredible dinosaur.

Tyrannosaurus rex T-rex T.rex Stan the T-rex

Here is one of the most famous T.rex skulls of all time. This specimen nicknamed "Stan", in honor of amateur paleontologist Stan Sacrison, was found in the Hell Creek Formation near Buffalo, South Dakota, in the spring of 1987. After 30,000 hours of digging and preparing, a 65% complete skeleton emerged. This tyrannosaur was found to have many bone pathologies, including broken and healed ribs, a broken (and healed) neck and a spectacular hole in the back of its head, about the size of a front lower *Tyrannosaurus* tooth.

Please inquire about other specimens.

Resin cast: \$9,500.00 (crating and shipping not included)

Tyrannosaurus rex Tooth Progression Partial Dentary cast replica

Tyrannosaurus rex Tooth Progression Partial Dentary cast replica

Late Cretaceous - Maastrichtian Locality: Hell Creek Formation, Harding County, South Dakota

This reconstruction, showing Tyrannosaurus rex tooth progression, provides a fascinating look inside the tooth regeneration process of the most fierce predator North America has ever hosted.

The exterior of the dentary is intact, while the interior provides an open window to the innermost actions taking place. The Theropod dinosaurs regrew their teeth as the old ones became too worn or broke off. The blood vessels and soft tissues would have transported the raw materials necessary for healthy teeth and bone as these massive giants continually regenerated their fearsome smile and devastating bite."

T-rex partial dentary resin cast: measures: 11x11x3.5 inches

Uintatherium Skeleton fossil cast replica

Uintatherium is an extinct genus of mammals. Fossil remains were discovered near Fort Bridger, Wyoming. This was a large browsing animal, about the size of a rhinoceros. What was most unusual about *Uintatherium* was its skull which was large and strongly built. Uintatherium had a flat, concave skull a feature not found in any other mammal, save, perhaps in some brontotheres. Its cranial capacity was exceptionally small due the walls of the

Uintatherium Skeleton Rare and exotic dinocerta mammal of Eocene Uinta Colorado. Gunma MNH (Japan).

Available mounted: \$21,650 or \$16,000.00 unmounted (plus shipping)

cranium being tremendously thick. The weight of the skull was mitigated by numerous sinuses permeating the walls of the cranium, like those in an elephant's skull. The large upper canines were apparently formidable defensive weapons and were larger in males than in females.

The skulls of the males bore six prominent knob-like ossicones (horn-like or antler-like protuberance) which grew from the frontal region of the skull. The function of these structures is unknown. They may have been of used for defense or display. *Uintatherium* lived during the early to middle portions of the Eocene. It was an herbivore, eating leaves, grasses and shrubs. *Uintatherium* lived near water and used its sabre-like canines to pluck the aquatic and marsh plants which comprised its diet. It became extinct by climatic changes and competition with brontotheres, and true and hyrachodont rhinocerii without leaving any descendants.

Zygorhiza, skull

Zygorhiza kochii ("Koch's Yoke-Root") is an extinct species of cetacean. A Eocene Whale Skull & The Mississippi State Fossil

Zygorhiza was a smaller, less elongated, 6 m (20 foot) long relative of the famous *Basilosaurus*. *Zygorhiza* had flippers which could, unlike in modern cetaceans, be moved at the elbow. Its hind limbs were rudimentary. *Zygorhiza's* one-metre (3-foot) skull had fearsome jaws with deadly teeth. Unlike modern cetaceans, *Zygorhiza* had a neck consisting of seven vertebrae.

Complete skeleton also available.

We give something back

We give a percentage of our sales to various charities. Please help us support the causes we believe in.

Tucson Fossil, Gem and Mineral Show (Tucson, Arizona)
